As the name says it only gives concepts so it doesn't go into any great detail about a particular OS. The book has 15 pages on semaphores (15 pages sounds like a lot, but the text is not dense). You are not going to be an expert on semaphores but you will get the basic "concepts" of them.

Many embedded systems can be characterized as real time. A real-time system is one in which the correctness of the computations not only depends on their logical correctness, but also on the time at which the result is produced. In other words, a late answer is a wrong answer. As an example of a real-time

An embedded system is an electronic system that are designed to perform a dedicated function within a larger system. Real-time systems are those that can provide guaranteed worst-case response times to critical events, as well as acceptable average-case response times to noncritical events.

Embedded systems are also known as real time systems since they respond to an input or event and produce the result within a guaranteed time period. This time period can be few microseconds to days or months. Real time systems are further classified as hard real time systems and soft real time systems, based on the strictness to the time period.
